The impact of Jigsaw and STAD on social studies pre-service teachers' academic achievement*

Aşkın Baydar1, Ufuk Şimşek2

Abstract

The aim of this study is to compare two cooperative learning methods, jigsaw and student teams achievement divisions (STAD), in terms of their effects on social studies pre-service teachers' academic achievement. The study group of the research consisted of 40 students who attended teaching principles and methods course at Artvin Çoruh University College of Education Department of Social Science Education. Data was collected during 12 weeks implementation and with Academic Success Test (AST) which was developed by the researcher and was analyzed with independent samples t-test and one way analysis of variance (ANOVA). The findings of the research show that STAD is more effective than jigsaw on social studies pre-service teachers' academic achievement. Research also includes the recommendations for future applications.

Keywords: Cooperative learning, jigsaw, STAD, academic achievement, teacher education

Introduction

Today’s education should make students overcome the difficulties that they would face in work environment and everyday life. For this reason, “students not only need knowledge but also communication skills, problem solving skills, creative and critical thinking skills in the years ahead” (Zakaria & Iksan, 2007, p. 36). Therefore, it seem that teacher centered, traditional methods which are criticized for not attaching
enough importance to problem solving and critical thinking skills (Hannafin & Land, 1997), give their place to the learning methods which consider different thinking techniques and participation. Cooperative learning is one of these methods that is student centered and aimed to improve social skills. In teacher centered classes “students become passive recipients of knowledge and resort to rote learning. The majority of work involved teacher-talk using either a lecture technique or a simple question and answer that demand basic recall of knowledge from the learners” (Zakaria & Iksan, 2007, p. 35). In cooperative learning groups on the other hand, “students are employing their social skills to help all group members to achieve and to maintain effective working relationships within the group” (Johnson, Johnson, Holubee, & Roy, 1984, p. 8).

In traditional learning groups students usually study individually and the system is competitive (Slavin, 1977). In individualistic and competitive models students are evaluated independently and generally with comparing with each other. This system is being criticized for many years. On the other hand new research shows that cooperative teaching techniques provides much more academic achievement and social development than traditional methods (Slavin, 1978). “An individualistic goal structure is one in which students are given individual goals, and by using a criterion-referenced evaluation system students are assigned individual rewards. Whereas student interdependence is required in the cooperative structure, students behave quite independent of each other in an individualistic structure. Individualistic structures usually use a criterion-referenced evaluation system” (Sherman, 1991, p. 5); however in cooperative learning “by sharing their knowledge with each other in small groups working toward a common goal, students can benefit from distributed cognition, where the strengths of one student complement the needs of another, and each increases her knowledge base” (Coke, 2005, p. 385).

In “cooperative learning, that has been widely researched and used in classrooms around the world since the 1970s” (Vaughan, 2002, p. 359). Cooperative “teams are evaluated and/or rewarded on the basis of how much each member improves; because each student's achievement increases the success of the total team members work toward a common goal (Ascher, 1986, p. 2). An effective communication occurs
among the members work together and students force their minds with thinking and discussing (Bayrakçeken, Doymuş, & Doğan, 2013). “Cooperative learning groups are based on positive interdependence among group members, where goals are structured so that students need to be concerned about performance of all group members as well as their own” (Johnson et al., 1984, p. 9).

Jigsaw and STAD are among the most well-known (Kagan, 1989) and most widely used (Leming, 1985) structures of cooperative learning. Also according to Slavin and Karweit (1979), these two methods are among the most extensively researched and according to Zetty (1992), well-researched and highly touted cooperative learning methods.

In accordance with the findings above, the research problem is stated as “what are the effects of jigsaw and student teams achievement divisions (STAD) on social studies pre-service teachers’ academic achievement.

Method

The independent variables of the study are two of the cooperative methods, jigsaw and STAD; and the dependent variable of the study is social studies pre-service teachers’ academic achievement level. To measure the effects of these two cooperative methods on dependent variable pretest-posttest, no control group design was chosen. In this type of design, pretest is given to group or groups before the experimental process start. After finishing the experimental process the same test is given as the posttest (Sönmez & Alacapınar, 2011, p. 56).

Research Design

In the study a quasi-experimental design was used. It is common situation that educators do not prefer true experimental design in their researches. Because, randomly selection of classes and students that are necessary for the research, is almost impossible (Cohen, Manion, & Morrison, 2000). Karasar (2005) also took attention to the difficulties of the studies conducted in ministerial schools in Turkey.
and creating equal experimental groups. In such situations quasi-experimental designs were preferred.

**Study Group**

The study group of the research consisted of 40 students who attended teaching principles and methods course at Artvin Çoruh University College of Education Department of Social Studies Education. The class was divided to two homogenous experimental groups: jigsaw (n=20) and STAD (n=20) implementation groups. The homogeneousness of two groups was determined according to the grade point averages of the previous year.

**Data Collection Tool**

Academic Achievement Test (AAT), which was developed by the researcher, was used in the study. To measure the validity and reliability of the test, a pilot study which is a 50 question test was conducted with 150 students, who took the methods and principles of instruction course before.

Within the scope of the validity studies of the achievement test, making factor analysis for each item in the item pool, degree of difficulty and index of distinctiveness of each item were determined. Degree of difficulty of the items was found as between .11 and .97, and index of distinctiveness of the items was found as between .04 and .61.

Accordingly, it is understood that some items in the item pool are not convenient to the indexes of item difficulty and distinctiveness these items were extracted from the achievement test. Average item difficulty of the test, which consists of the remaining 30 items, was determined as .53. This result shows that the test has an average difficulty. The average distinctiveness of the test is calculated as .32. Thus, a fair level of distinctiveness was determined. Besides, it was determined that all the items in the achievement test are at an acceptable level. In accordance with the expert opinions and item analysis results, it can be said that the validity of the 30 question achievement test is high.
To calculate the reliability of the study, Kuder-Richardson-20 reliability coefficient was used. At the end of the analysis the reliability coefficient was stated as .68 and reached to the result that the achievement test is reliable.

**Data Collection**

After applying the AAT to both jigsaw and STAD groups as pretest, teaching principles and methods course was committed in both two experimental groups for 12 weeks by the researcher. At the end of the implementation process AAT was applied to the experimental groups as posttest. The implementation processes of jigsaw and STAD methods in experimental groups were explained below.

**Implementation of Jigsaw**

For implementing the method, students were separated into five original groups. Each group has 4 members.

Figure 1. Jigsaw original groups and distribution of titles

After assigning the original groups, subtitles were distributed to each member of the original groups as in Figure 1. Subtitles they are responsible of and related materials were given to the each member of the groups. Then, members left from the original groups and were assigned to the expert groups as in Figure 2. Each subtitle was in one expert group’s expertise area.
After giving or suggesting necessary resources by the researcher, each expert group got ready to their subtitle in union until the next class. These preparations involve both individual and group studies in homes, dormitories, and libraries.

The expert groups came to class with materials that they studied individually or together on. They had 30 minutes to study the materials they brought, discuss, combine the studies and review. At the end of this time, each expert group finished and reported their study on the subtitle they specialized on, with a report. During all the studies researcher worked as a guide in case of possible questions, problems.

After finishing the studies in expert groups, participants returned their original groups and each original group member share her study that she prepared in the expert group with a presentation. 30 minutes were given to original groups for this part of the study including the time for question-answer and discussing.

At the last step of the implementation in jigsaw group, all the participants took a four question, multiple-choice quiz. The answers were given to the participants, right after the quiz. And then they were given 20 minutes to correct their deficiencies.

**Implementation of the STAD**

Like in jigsaw group, the implementation process of the method was explained in details to the STAD group by the researcher in the first hour of the course. And like in jigsaw group, titles were divided in subtitles and committed starting with the second week of the semester and during 12 weeks. Considering AAT pretest results the participants heterogeneously grouped in fours same as in jigsaw group.
After distributing the students to groups, researcher made a 40 minutes presentation. During 12 weeks implementation process, researcher used techniques like direct instruction, question-answer, and visual presentation dependently on the characteristics of subjects. Following the researcher’s presentation, participants went to the groups they assigned and started to “team study”. For this study to provide interdependency in group, one work sheet was given to each two participants. Groups have 40 minutes to complete their studies. During all the studies researcher worked as a guide and answer the questions if nobody could in the group.

Finishing team studies, participants took a four question quiz. Also for each participant, 5 points below was accepted as her “starting point”. By comparing the starting point and quiz score, “individual improvement score” was determined. And with the sum of individual improvement scores of each member in teams, the “team scores” were provided. Lastly, to appreciate the successful team, team scores were announced to whole class.

**Data Analysis**

Data were analyzed with SPSS and using independent samples t-test and one way analysis of variance (ANOVA).

**Findings**

For understanding if any significant difference between pretest points to make test of normality first and because number of participants is lower than 50, to determine distribution of data, Shapiro-Wilk test was made (Shapiro & Wilk, 1965). The results of Shapiro-Wilk test showed that pretest point averages of both two groups have a normal distribution. Thus, to compare jigsaw and STAD groups’ pretest point averages independent samples t-test was used.
Table 1. Independent samples t-test results regarding Jigsaw and STAD groups’ AAT pretest point averages.

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

As stated in Table 1, at the end of the independent groups t test it was determined that there is no significant difference between social studies pre-service teachers’ academic achievement pretest points ($t_{(38)} = .60$, $p > .05$).

To determine the effects of jigsaw and STAD on social studies pre-service teachers’ academic achievement, one way analysis of variance (ANOVA) was used. For this purpose, a statistical process was applied by taking the mean difference of pretest and posttest points of social studies pre-service teachers in jigsaw and STAD groups.

</tbody>
</table>

As seen in Table 2, at the end of the ANOVA it is determined that there is significant difference regarding the mean difference of jigsaw and STAD groups’ academic achievement pretest and posttest points ($F_{(1, 38)} = 12.19$, $p < .005$).
The study reached to the conclusion that using jigsaw and STAD is effective on pre-service teachers’ academic achievement. To understand that which group was more effective, Tukey test, which is one of the PostHoc test, was done. At the end of the analysis, jigsaw group’s pretest-posttest mean difference ($X=1.10, Ss=3.66$) was found lower than STAD group’s pretest-posttest mean difference ($X=4.85, Ss=3.09$), ($p<0.05$).

**Discussion, Conclusion and Implications**

Academic achievement which is the dependent variable of the study was increased in STAD group significantly at the end of the study. This situation verifies Slavin’s (1991, p. 90) statement that “STAD are most appropriate for teaching well-defined objectives with single right answers. Because, both Academic Achievement Test that was applied pretest and posttest in teaching principles and methods course the experimental process applied in, and the quizzes are consisted of single answer, multiple choice questions.

The results of this study that compares jigsaw and STAD in terms of their effects on academic achievement overlaps with Slavin’s (1980) results he reached with six different studies that to improve the basic skills in mathematics and language lessons STAD is more effective than jigsaw. In another study (Zetty, 1992) that compares jigsaw and STAD different results were found. In that study jigsaw was found more effective than STAD.

This study that shows the positive effects of STAD, gave similar results with Tiantong & Teemuangsai (2013), Jalilifar (2010) and Brooks’s (2009) studies that conducted with university students. Also Slagle’s (2009) study, which done by trying STAD in secondary school social studies course, has similar results overlap the results with this study. The results of this study, support the results of the studies (Amornsinlapahchai, 2014; İbraheem, 2011; Efe, 2011; Gençosman, 2011; Conring, 2009; Özsar, 2009; Tarim & Akdeniz, 2008; Alkaya, 2006; Bilgin, 2004; Vaughan, 2002) that tried STAD in elementary and secondary schools. But they do not support the results of Erdoğan (2008), Gelici & Bilgin (2007), Ergin (2007); Yıldırım-Kayabaş (2007) and Slavin (2007)’ studies.
On the other hand, jigsaw is less effective than STAD on pre-service teachers’ academic achievement and this situation is consistent with the studies (Arslan, 2012; Fies, 2008; Ross, Seaborn, & Wilson, 2002; Holliday, 1995; Webb, 1992) in the area that jigsaw was compared with and could not found any significant effect. But in the literature there are also studies (Şimşek, Örten, Topkaya, & Yılar, 2014; Huang, Liao, Huang, & Chen, 2014; Evcim & İpek, 2013; Jurhill, 2011; Öner, 2007; Avşar & Alkış, 2007; Şimşek, 2007; Acar, 2006; Wang, 2006; Sönmez, 2005) that jigsaw is more effective than the methods compared with in terms of academic achievement and their results are not consistent with this study. With its results the research suggests to prepare curriculums that would pave the way for cooperative methods to take places in schools and teacher education adequately.
